Herein, we have designed and synthesized a electrode made up of NiFe_{2}O_{4} nanosheets grown on three-dimensional nickel foam (NiFe_{2}O_{4}/NF) via a facile hydrothermal method. As a pseudocapacitor, the as-prepared NiFe_{2}O_{4}/NF electrode exhibited a relatively high capacitance (975 F g^{-1} at current density of 1 A g^{-1}), excellent cycle life (about 95% capacitance retention after 3000 charge-discharge cycles at 10 A g^{-1}) and good rate capability (74.6% capacitance retention from 1 to 10 A g^{-1}). This work not only shows a simple way to enhance high electrochemical performance, but also demonstrates that the prepared freestanding NiFe_{2}O_{4}/NF electrode could be a potential electrode material for high performance supercapacitors.

Keyword: Fe-Ni double oxides, nanosheets, nickel foam, supercapacitor

1. INTRODUCTION

Sustainable and renewable clean resources have attracted significant research attention due to the fast development of the worldwide economy, the persistent consumption of fossil fuels, the deepening crisis of environmental pollution, the rapid expansion market for mobile electronic devices[1-5]. Among numerous energy conversion and storage devices, supercapacitors have attracted great interest in the past decades due to the fast charging and discharging rate, high reliability, long cycle lifetime, and high-power density [6-10]. Supercapacitors, also called electrochemical capacitors (ECs), which have three main kinds of electrode materials, including carbonaceous materials [11], metal oxides/hydroxides [12,13], and conducting polymers [14]. However, due to the physical charge accumulation through the reversible adsorption/desorption of ions at the electrode/electrolyte interface, carbon-based electrode materials usually show low energy density. Consequently, metal oxides, hydroxides and conducting
polymers directly store charges during the reversible and fast faradaic redox reactions occurring on the surfaces, which produces relatively high energy density.

Recently, many transition metal oxides-based ECs have caused the extensive concerns, such as hydrous RuO$_2$ [15], Fe$_2$O$_3$ [16], Co$_3$O$_4$ [17], NiO [18,19], MnO$_2$ [20], V$_2$O$_5$ [21]. Interestingly, binary transition metal oxide materials have been attracting lots of attentions for the synergistic effect from the both metal ions, such as Co-Ni double oxides [22], Fe-Co double oxides [23], Mn-Ni double oxides [24], Mn-Fe double oxides [25] and Fe-Ni double oxides [26,27]. However, the electrochemical performance of those binary oxides also trapped due to their innate weakness such as low electroconductivity, strong tendency aggregation and limited effective active surface area. Consequently, to overcome these issues, scientists utilized a series of three-dimensional (3D) conductive architecture with high electrical conductivity to enhance the electrochemical activity. Thus, herein, we have designed and synthesized a series of NiFe$_2$O$_4$ nanosheets grown on 3D nickel foam (NiFe$_2$O$_4$/NF) via a facile hydrothermal method. Remarkably, the NiFe$_2$O$_4$/NF electrode exhibited a relatively high capacitance (975 F g$^{-1}$ at current density of 1 A g$^{-1}$), excellent cycle life (about 95% capacitance retention after 3000 cycles at 10 A g$^{-1}$) and good rate capability (74.6% capacitance retention from 1 to 10 A g$^{-1}$). This work not only shows a simple way to enhance high electrochemical performance, but also demonstrates that the NiFe$_2$O$_4$/NF can be considered as an appealing efficient electrode for supercapacitor.

2. EXPERIMENTAL

2.1. Material synthesis

All chemicals are of analytical grade and used as received without further purification. The deionized water was used in all experiments. Commercial nickel foam (NF) with a thickness of 1.2 mm were cut into size of 2×4 cm$^2$, and was cleaned by sonication in 1 M HCl solution, absolute ethanol and deionized water for 20 min to remove the surface oxide layer and oil stain. Then the wet NF was dried at 80 ºC for 12 h. In a typical synthesis of NiFe$_2$O$_4$/NF electrode, 0.139 g of FeSO$_4$·7H$_2$O, 0.0727 g of Ni(NO$_3$)$_2$·6H$_2$O and 0.09 g of CO(NH$_2$)$_2$ were dissolved in 30 mL of deionized water by magnetic stirring. Then a piece of treated NF was impregnated into the solution, and the reaction was transferred into a 50 mL Teflon-lined stainless autoclave and maintained at 180 ºC for 12 h. After natural cooling to room temperature, the product was washed with mixed liquids with deionized water and ethanol, and then dried at 60 ºC for 12 h in vacuum oven, subsequently the Fe-Ni layered double hydroxide (FeNi-LDH) on the Ni foam were obtained. Finally, the NiFe$_2$O$_4$/NF composites were achieved by annealing the above product in a muffle at 350 ºC for 2 h with a heating rate of 2 ºC min$^{-1}$. The mass loading of NiFe$_2$O$_4$ is about 1.0 mg cm$^{-2}$. In addition, NiFe$_2$O$_4$ powder samples were also obtained by the same experimental conditions without adding the NF.

2.2. Material characterization and electrochemical measurements

The X-ray diffraction (XRD) patterns were recorded on an X-ray diffractometer (type HZG41BPC) with Cu Ka irradiation source ($\lambda = 0.15418$ nm) at a scan rate (20) of 0.05 os$^{-1}$. SEM images were observed with S4800 field emission scanning electron microscope (FESEM, Hitachi, Japan) on the voltage of 7.5 kV. EDX using an instrument equipped in the FESEM. X-ray photoelectron
spectroscopy (XPS) measurements were performed on a Kratos XSAM800 XPS system with Al Kα source and a charge neutralizer, and all the binding energies were referenced to the C 1s peak at 284.8 eV of the surface adventitious carbon. TEM images were obtained with a JEM-2100F electron microscope (JEOL, Japan). The accelerating voltage and the applied current were 50 kV and 100 mA. The electrochemical properties of the prepared samples were investigated by cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS) and galvanostatic charge-discharge (GCD) measurements with an electrochemical workstation (CHI760E Instruments, Shanghai Chenhua Instrument Crop., Shanghai, China). The electrochemical behavior of the active materials was tested with three-electrode system in a 2 M KOH electrolyte at room temperature, where NiFe-LDHs/rGO acted as working electrode, an Ag/AgCl and a 1.5×1.5cm2 Pt plate were used as the reference and counter electrode.

NiFe2O4/NF sample could be used directly as working electrode with 1×1 cm2. For powder materials, to prepare the working electrodes, a mixture of active materials, acetylene black and polyvinylidene fluoride (mass ratio 8:1:1) was dispersed in N-Methyl pyrrolidone (NMP) solvent to obtain a slurry. After painting onto a clean nickel foam (1×1 cm2), the electrode was dried at 80 oC overnight. The mass loading of active materials for individual electrodes was about 1.0 mg cm-2. The electrochemical characterization of individual electrode was tested with three-electrode system in 2 M KOH electrolyte at room temperature, where Ag/AgCl and a platinum foil were used as the reference and counter electrodes, respectively. Cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS) and galvanostatic charge/discharge (GCD) measurements were performed using an electrochemical workstation (CHI 760E Instruments, Shanghai Chenhua Instrument Crop., Shanghai, China).

3. RESULTS AND DISCUSSION

The morphology and microstructure of pure nickel foam and NiFe2O4/NF samples were observed by the field-emission scanning electron microscopy (FESEM). As shown in Fig. 1a, the pure Ni foam shows a three-dimensional porous framework structure with smooth surface. Correspondently, almost all the surface of NiFe2O4/NF sample (Fig. 1b) becomes rougher than the original Ni foam, implying that NiFe2O4 was uniformly deposited on the Ni foam. The magnified FESEM images (Fig. 1c and 1d) further indicate the sheet-like structure of NiFe2O4, and these thin nanosheets are interconnected and perpendicularly grown on the surface of Ni foam.
Figure 1. FESEM images of (a) pure nickel foam and (b-d) NiFe$_2$O$_4$/NF sample at different resolutions.

Figure 2. FESEM image and corresponding EDX elemental mappings of Ni, Fe and O from NiFe$_2$O$_4$/NF.

The FESEM and the corresponding elemental mapping images were shown in Fig. 2, the expected presence of Ni, Fe and O elements can be clearly observed. After strong ultrasonic vibration, the NiFe$_2$O$_4$ nanosheets were exfoliated from Ni foam and observed by TEM test. As shown in Fig. 3, the TEM images clearly indicate a thin plate-like structure of NiFe$_2$O$_4$. The SAED pattern (inset in Fig. 3b) obtained from a typical nanoplate shows a highly symmetrical dotted lattice, suggesting the single-crystalline characteristic of the sample. The HRTEM image of the nanosheet (Fig. 3c) shows a clear
lattice spacing of 0.25 nm, which can be attributed to the (311) plane of NiFe$_2$O$_4$. Due to the low content of NiFe$_2$O$_4$ in NiFe$_2$O$_4$/NF composite (1.0 mg cm$^{-2}$) and the strong diffraction peaks of Ni form, there is no obvious characteristic peaks of NiFe$_2$O$_4$ can be detected from the XRD pattern of NiFe$_2$O$_4$/NF hybrid samples. Consequently, the XRD patterns of pure NiFe$_2$O$_4$ and FeNi-LDH samples without Ni foam are presented in Fig. 3d. For FeNi-LDH sample, the sharp diffraction peaks appear at around 10.4 and 22.8° can be assigned to (003) and (006) planes, exhibiting the typical characteristics of layered double hydroxide materials. In addition, all the diffraction peaks can be indexed to FeNi-LDH (JCPDS card No. 40-0215) [28]. After annealing, all the strong diffraction peaks can be corresponded to NiFe$_2$O$_4$ with a cubic spinel crystalline structure (JCPDS card No. 10-0325), implying the full transformation of FeNi-LDH to NiFe$_2$O$_4$.

X-ray photoelectron spectroscopy (XPS) was carried out to confirm the existence of NiFe$_2$O$_4$ and NF in the composites and to analyze their surface chemical states. In Fig. 4a, the survey spectrum of NiFe$_2$O$_4$/NF sample confirms the existence of O, Fe, Ni and C elements, which further demonstrates the high purity of the product. The characteristic peaks observed in the O1s in Fig. 4b can be decomposed into three constituents at 530.1, 531.5 and 532.5 eV, assigning to metal-O bonds, metal-O-H and surface-adsorbed water molecules, respectively [29,30]. As shown in Fig. 4c, the XPS spectrum of Fe 2p showed binding energies of Fe 2p$_{3/2}$ and Fe 2p$_{1/2}$ at around 712.3 and 724.7 eV, respectively, suggesting the coexistence of Fe$^{2+}$ and Fe$^{3+}$ [31,32]. In addition, as can be seen in Fig. 3d, the fitting peaks at 855.7 and
873.3 eV can be attributed to Ni 2p_{3/2} and Ni 2p_{1/2} (the spin-energy separation is about 17.6 eV), while the peaks at 861.7 and 879.6 eV are two shake up satellite peaks, indicating the +2 oxidation state of Ni (Ni^{2+}) in the sample [33].

The electrochemical activity of the as-prepared NiFe₂O₄/NF sample as a binder-free electrode was investigated by cyclic voltammetry (CV) and galvanostatic charge-discharge (GCD) technique in a traditional three-electrode system by using 2 M KOH as the aqueous electrolyte. The CV curves of NiFe₂O₄/NF sample in a potential window of 0 - 0.5 V (vs. Ag/AgCl) at scan rates ranging from 5 to 50 mV s⁻¹ are shown in Fig. 5a. Obviously, all the CV curves exhibit similar shape and show a set of intense redox peaks, revealing that the specific capacitance can be attributed to the reversible and fast electrochemical redox reactions [34,35]. Clearly, the peak potential shifts less than 100 mV with increasing the scan rates from 5 to 50 mV s⁻¹, reflecting that the working electrode has low polarization. The CV curves at the scan rate of 30 mV s⁻¹ for NiFe₂O₄/NF, NiFe₂O₄ and NF samples are shown in Fig. 5b. Clearly, the CV curve of pure NF is nearly a straight line, thus, the capacitance of NF can be neglected on this occasion. Importantly, the NiFe₂O₄/NF electrode shows a much larger integrated CV area than that of NiFe₂O₄ sample, indicating the better capacitive property [36]. These results directly reveal the
advantage of anchoring electrode materials on NF to be used as binder-free electrodes for capacitance improvement.

![Figure 5. (a) CV curves of NiFe$_2$O$_4$/NF at different scan rates ranging from 5 to 50 mV s$^{-1}$; (b) CV curves of pure NF, NiFe$_2$O$_4$ powder and NiFe$_2$O$_4$/NF at a scan rate of 30 mV s$^{-1}$.](image)

To further assess the specific capacitance of the NiFe$_2$O$_4$/NF electrode, GCD measurements were carried out at different current densities ranging from 1 to 10 A g$^{-1}$ with the potential window of 0 to 0.4 V. The $C_s$ (specific capacitance) value of the electrode can be evaluated by the discharge time according to eq. (1):

$$C_s = \frac{I \times \Delta t}{m \times \Delta V}$$

(1)

where $I$, $\Delta t$, $m$, and $\Delta V$ represent discharge current, time, the mass of the active material in the electrode and potential window, respectively. As shown in Fig. 6b, the NiFe$_2$O$_4$/NF electrode exhibits a high specific capacitance of 975 F g$^{-1}$ at the low current density of 1 A g$^{-1}$ and maintained a capacitance of 727 F g$^{-1}$ at a high current density of 10 A g$^{-1}$. The retention ratio is about 74.5%, indicating the excellent rate capability. The high specific capacitance of the prepared NiFe$_2$O$_4$/NF electrode is superior or comparable to most of the recently reported spinel transition metal oxide-based electrode materials.
To further clarify the transport kinetics for electrochemical reaction process, electrochemical impedance spectrum (EIS) test was carried out and the Niquist plots of NiFe$_2$O$_4$/NF and NiFe$_2$O$_4$ are shown in Fig. 7a. Obviously, the Niquist plot of NiFe$_2$O$_4$/NF electrode is almost linear, while the NiFe$_2$O$_4$ sample shows a quasi-semicircular arch at high frequencies and an oblique line at low frequencies. The smaller semicircle means a lower charge transfer resistance ($R_{ct}$) and a steeper slope illustrates a lower resistance of electrolyte ions [34]. These results clearly illustrated that the NiFe$_2$O$_4$/NF composite has a smaller $R_{ct}$ and exhibits a nearly ideal capacitive behavior with fast electrolyte ion diffusion, resulting in fast charge transformation and high electrolyte accessibility, thus enhancing the specific capacitance. The cycling stability of the electrode is another important parameter for practical application of the supercapacitors, which precisely reflects the service performance, is also investigated in our study. Fig. 7b shows the cycling ability of as-synthesized NiFe$_2$O$_4$/NF electrode for 3000 cycles at current density of 10 A g$^{-1}$. Significantly, the specific capacitance of NiFe$_2$O$_4$/NF electrode decreases slightly with an outstanding retention of about 95% after 3000 cycles, suggesting the excellent stability for long time charge-discharge applications. Also, the calculated electrochemical results of the NiFe$_2$O$_4$/NF electrode are compared with previous reports (Table 1). The enhanced electrochemical performance of NiFe$_2$O$_4$/NF electrode can be attributed to the specific 3D Ni foam framework with the NiFe$_2$O$_4$ nanosheets vertically grown on the surface. The intimate contact between NiFe$_2$O$_4$ nanosheets and 3D Ni foam through the in-situ growth method and such unique hierarchical structure are benefit for the electrical conductivity and diffusion kinetics, thereby enhancing the specific capacitance.

4. CONCLUSIONS

In summary, we have successfully developed a freestanding electrode made up of NiFe$_2$O$_4$ nanosheets grown on 3D nickel foam via a facile hydrothermal method. As a pseudocapacitor, the as-prepared NiFe$_2$O$_4$/NF electrode exhibited a relatively high capacitance of 975 F g$^{-1}$ at 1 A g$^{-1}$, excellent cycle life (about 95% capacitance retention after 3000 charge-discharge cycles at 10 A g$^{-1}$) and good rate capability (74.6% capacitance retention from 1 to 10 A g$^{-1}$). Such excellent capacitive behaviors of the NiFe$_2$O$_4$/NF electrode are mainly ascribed to the intimate contact between NiFe$_2$O$_4$ nanosheets and Ni foam and the unique hierarchical 3D structure. This work not only shows a simple way to enhance...
high electrochemical performance but also shows that the freestanding NiFe$_2$O$_4$/NF electrode can be considered as an appealing candidate electrode for supercapacitors.
